

Improve Code Quality and Readability

Code Review and Quality: Using AI to

2303A51682

Lab-10.3

Problem Statement 1: AI-Assisted Bug Detection Given

Code :

```
def factorial(n):  
    result = 1    for i in  
range(1, n):  
    result = result * i  
return result
```

Testing

```
print(factorial(5))
```

Output:

24

Issue Identified

The function contains an **off-by-one error**.

The loop `range(1, n)` stops at `n-1`, so it does not multiply by `n`.

Corrected Code

```
def factorial(n):
```

```

    if n < 0:
        raise ValueError("Factorial is not defined for negative numbers")
    if n == 0:
        return 1

    result = 1
    for i in range(1, n + 1):
        result *= i
    return result

```

Correct Output:

120

Comparison

Manual Fix

Fixed range to n+1

No edge case handling

AI improved robustness by handling edge cases.

AI Fix

Fixed range and added validation

Handles negative & zero cases

Problem Statement 2: Improving Readability & Documentation

Original Code def calc(a, b, c): if c == "add": return a + b

elif c == "sub":

return a - b

elif c == "mul":

return a * b elif c

```
== "div":  
    return a / b
```

Issues

- Poor function name (calc)
- No documentation
- No exception handling
- No input validation

```
Improved Code def calculate(number1,  
number2, operation):  
    if not  
    isinstance(operation, str):  
        raise TypeError("Operation must be a string")  
  
    if operation == "add":  
        return number1 + number2  
    elif operation == "sub":  
        return number1 - number2  
    elif operation == "mul":  
        return number1 * number2  
    elif operation == "div":  
        if  
        number2 == 0:  
            raise ZeroDivisionError("Cannot divide by zero")  
        return number1 / number2  
  
    else:  
        raise ValueError("Invalid operation")
```

Problem Statement 3: Enforcing PEP8 Standards

Original Code def Checkprime(n):

for i in range(2, n):

if n % i == 0:

return False return

True

PEP8 Violations

- Function name not in snake_case
- No input validation
- No docstring

Refactored Code def

check_prime(n):

if n <= 1:

return False

for i in range(2, n):

if n % i == 0:

return False return

True **Problem**

Statement 4: AI as a

Code Reviewer

Original Code

```
def processData(d):  
    return [x * 2 for x in d if x % 2 == 0]
```

Issues

- Poor naming
- No validation
- No type hints
- No documentation

Improved Code

from typing import List, Union

```
def double_even_numbers(numbers: List[Union[int, float]]) -> List[Union[int, float]]:
```

```
    if not isinstance(numbers, list):
```

```
        raise TypeError("Input must be a list")
```

```
    return [    num * 2    for num in numbers    if  
isinstance(num, (int, float)) and num % 2 == 0  
    ]
```

Reflection

AI should act as an **assistant**, not a replacement for human reviewers. It speeds up reviews but human judgment is still essential.

Problem Statement 5: AI-Assisted Performance Optimization

Original Code

```
def sum_of_squares(numbers):
```

```
    total = 0
    for num
```

```
        in numbers:
            total
```

```
            += num ** 2
    return
```

```
total
```

Time Complexity

$O(n)$

Optimized Code

```
def sum_of_squares_optimized(numbers):
```

```
    return sum(x * x for x in numbers)
```

Comparison

Original	Optimized
Uses manual loop	Uses generator expression
Slightly longer	More concise
Same time complexity	Cleaner implementation

Trade-off Discussion

- Optimized version improves readability.
- For very large datasets, NumPy can provide further speed improvements.
- Built-in functions are generally faster and more Pythonic.
